CONSUMER SELF-PERCEPTION · SHOPPING SIMULATION

Seeing the *Gap*

An interactive shopping-platform simulation for high school students

ZHIYAN ZHANG · SHANGHAI PINGHE SCHOOL

N = 41 COMPLETED SESSIONS

← → 翻页 · B 静态 · ESC 索引

How did a shopping simulation affect students' recognition of gaps between self-perception and choices?

Original hypothesis

The simulation would make this gap more visible after use.

How I read the result

A lower post-score can mean recalibration: students became less overconfident.

One tool, five shopping moments

SAMPLE
41 valid sessions

EVENTS
205 shopping-stage records

DATA
Supabase anonymous records

BOUNDARY
No real purchase or payment

MEAN CHANGE: POST - PRE

-0.593

The post-test self-rating was lower. I interpret this as students becoming less overconfident after seeing their own simulated choices.

PRE MEAN

3.821

POST MEAN

3.228

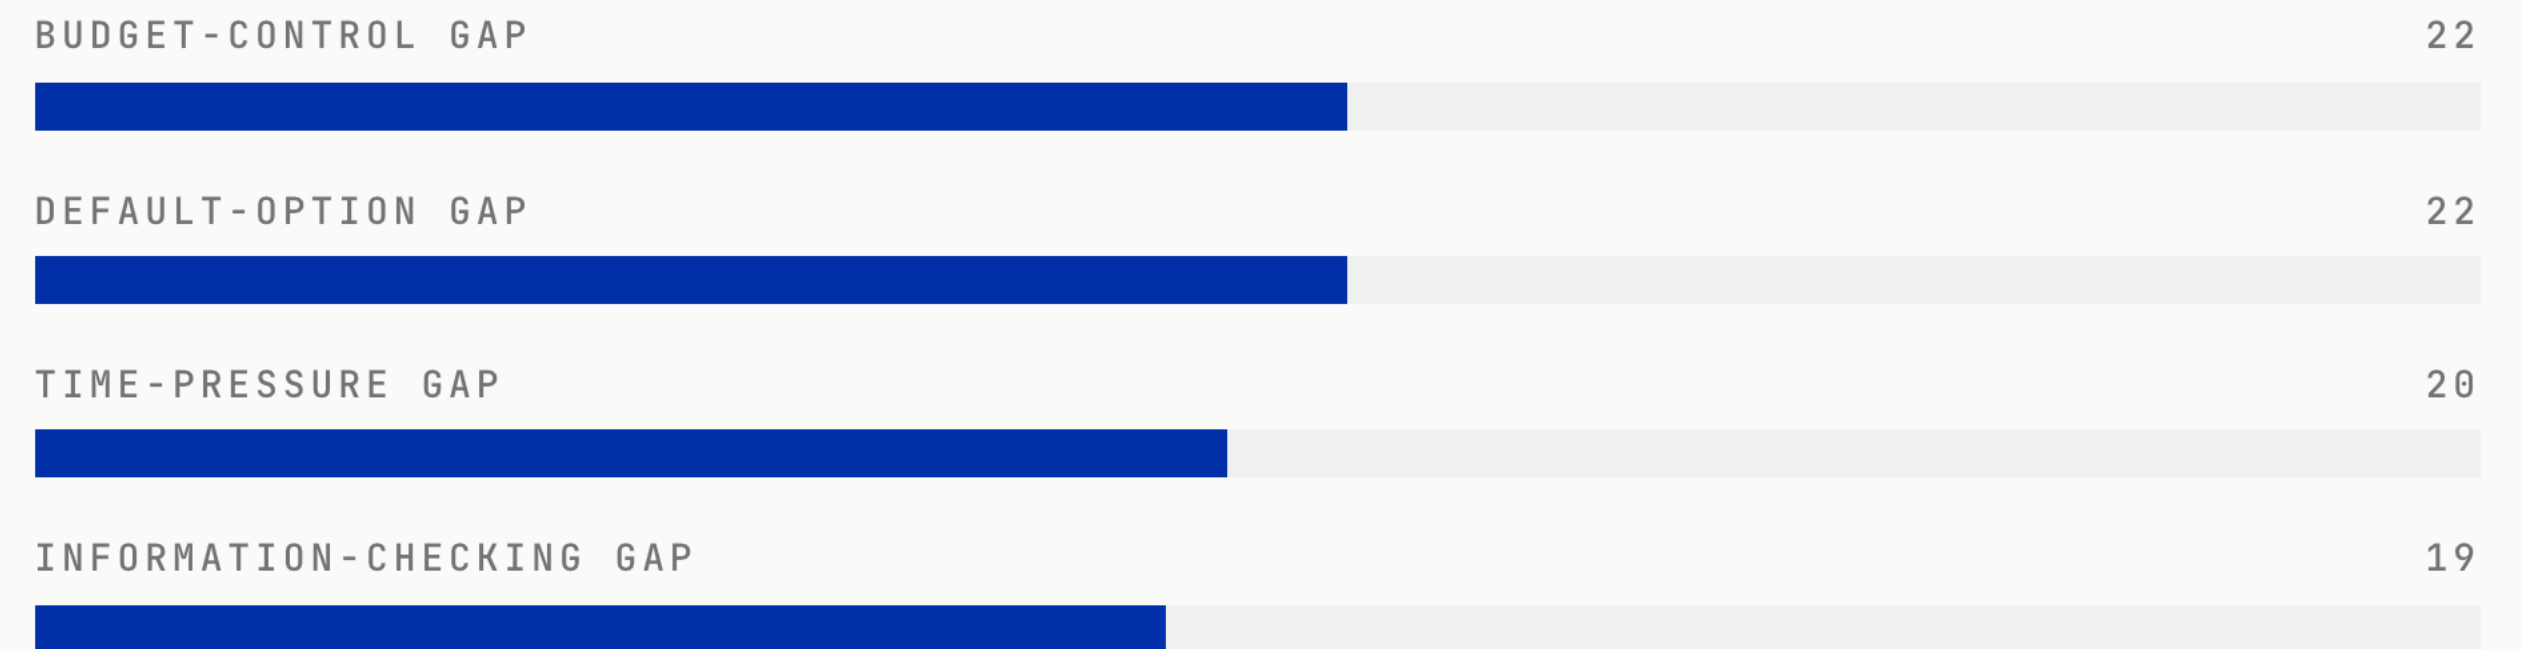

DECREASED

30 / 41

RULE-BASED MISMATCHES

31 of 41
had at
least one
gap.

Mismatch count and recalibration were strongly related: $r = 0.758$.

THE RESULT DID NOT FAIL THE PROJECT

It changed how the result should be read.

- 01 / FINDING

Recalibration

Students lowered confidence after seeing their own choices.

- 02 / MECHANISM

Interface cues

Defaults, discounts, reviews, and budget warnings shaped action paths.

– 03 / QUALITATIVE

Reflection

Open-text answers often named page elements that changed choices.

- 04 / LIMIT

Caution

Small voluntary sample; simulated platform; rule-based gaps are exploratory.

LIVE ARTIFACT

Try the simulation

- 01

Real records

41 completed anonymous sessions are analyzed.
- 02

Visible gaps

75.6% showed at least one self-perception/action gap.
- 03

Recalibration

The lower post-score suggests less overconfidence, not a failed result.
